

Suggestions from Yichen:

1. Some columns within our dataset are interpretable
 - a. Analyze which columns play a heavy role in determining the output, and if they are interpretable, use this in our presentation to provide business insights
 - b. Wenyu
2. Interactions of columns could be meaningful
 - a. E.g. Interaction of Age*account value
3. While many of the columns have lots of 0s, a user that has many non-zero columns may be a “heavy user” and their sentiments may be worth analyzing apart from the whole group
 - a. Clustering analysis first, (to group heavy users)
https://github.com/diefimov/santander_2016/blob/master/README.pdf
 - b. Wenyu
4. Some of the numerical columns have a large range of values, it may be worth sorting them into buckets as a “normalization” process
5. During model and hyperparameter exploration, we should try using models from different families
 - a. E.g. XG boost and Light GBM are within same family, want to compare or ensemble other model types
 - b. Austin
6. Can try a neural network or linear regression approach if we want
 - a. Joe
 - b. Hazel
7. Bayesian optimization for hyperparameter tuning may be faster but may not always give the best result
8. To deal with imbalanced data, try using class_weight to automatically adjust parameters
9. In Ensemble approach, is the ensemble layer considering the correct inputs?
 - a. E.g. Are we truly using a stacking approach?
